

### Exercise 3

1 Consider classifier  $h_1$  obtained from algorithm  $A$  for sample  $S$ .

Also, consider classifier  $h^* \in \mathcal{H}_{\text{rec}}^2$ , s.t.  $L_{(D, \epsilon)}(h^*) = 0$ . It exists due to the Realizability Assumption.

Then,  $L_S(h^*)$  is also equal to 0. Therefore, all positive examples are contained within rectangle of classifier  $h^*$ . Since rectangle of  $h_1$  is the smallest rectangle enclosing all positive examples, it must be located within borders of  $h^*$  rectangle.

Since  $L_S(h^*) = 0$ , all negative examples are outside of the  $h^*$  rectangle and, therefore, they are outside of the  $h_1$  rectangle.

Since all negative examples are outside of the  $h_1$  rectangle and all positive are inside, we get that  $L_S(h_1) = 0$ , hence  $A$  is an ERM.

### Exercise 3 cont.

[2] Since  $R^*$  is the rectangle that generates the labels, all positive examples are inside  $R^*$  and all negative are outside. Assume  $R(S)$  is not fully contained within  $R^*$ . Then, consider  $R(S) \cap R^*(S)$ . Since all positives are contained within both  $R(S)$  and  $R^*(S)$  and all negatives are outside of both  $R(S)$  and  $R^*(S)$ ,  $R(S) \cap R^*(S)$  is a rectangle enclosing all positive examples in the training set. But we know that  $R(S)$  is the smallest such rectangle, since it is obtained by  $A$ . Hence,  $R(S) \cap R^*(S)$  and  $R(S)$  are of the same size, and that means that  $R(S) \subseteq R^*(S)$ .

Now, if  $S$  has positive examples in all of the  $R_1, R_2, R_3, R_4$ , let's show that  $A$  has error at most  $\epsilon$ .

Let  $R(S) = R(a_1, b_1, a_2, b_2)$ . Since it has all positive examples and each of  $R_1, R_2, R_3, R_4$  have at least one, we get that  $a_1 \geq a_1^* \geq a_1^*$ ,  $a_2 \geq a_2^* \geq a_2^*$ ,  $b_1 \leq b_1^* \leq b_1^*$  and  $b_2 \leq b_2^* \leq b_2^*$ . Since probability mass of  $R(a_1, b_1, a_2, b_2)$  is at least probability mass of  $R^*$  minus sum of probability masses of  $R_1, R_2, R_3, R_4$ , we get that probability mass of the rectangle  $R(a_1, b_1, a_2, b_2)$  is at least  $1 - \epsilon$ . Since  $R(a_1, b_1, a_2, b_2)$  is fully contained within  $R(a_1^*, b_1^*, a_2^*, b_2^*)$ , probab. mass of  $R(S)$  is at least  $1 - \epsilon$ , hence hypothesis returned by  $A$  has error of at most  $\epsilon$ .

Let  $m$  be the size of the training set. Then for each point in the set, the probability that it is not contained within  $R_i$  is  $1 - \frac{\epsilon}{4}$  for each of  $i \in \{1, 2, 3, 4\}$ . Hence, for each  $i \in \{1, \dots, 4\}$ , the probability that  $S$  doesn't contain an example in  $R_i$  will be  $(1 - \frac{\epsilon}{4})^m$ .

Then, probability that  $S$  doesn't contain ~~any~~ positive example in at least one of  $R_i$ ,  $i \in \{1, \dots, 4\}$  will be equal to  $4(1 - \frac{\epsilon}{4})^m$ , which is smaller ~~than~~ or equal to  $4 \cdot e^{(-\frac{\epsilon}{4}) \cdot m}$ .

Hence, the probability that the hypothesis returned by  $A$  has error of at most  $\epsilon$  is <sup>larger</sup> ~~smaller~~ or equal to  ~~$1 - 4e^{(-\frac{\epsilon}{4}) \cdot m}$~~ . Let's denote this probability ~~as~~  $1 - \sigma$ .

Then,  $\sigma \leq 4e^{-\frac{\epsilon}{4} \cdot m}$  gives us inequality

$$m \geq \frac{4 \log(\frac{4}{\sigma})}{\epsilon}.$$

Hence, if  $A$  receives a training set of size  $m \geq \frac{4 \log(4/\sigma)}{\epsilon}$ , then with probability of at least  $1 - \sigma$  it returns a hypothesis with error of at most  $\epsilon$ .

[3] Let  $R^* = R^d(a_1^*, b_1^*, a_2^*, b_2^*, \dots, a_d^*, b_d^*)$  be  $d$ -dimension rectangle that generates the labels and let  $f$  be the corresponding hypothesis.

Let  $a_1 \geq a_1^*$  be a number, s.t. prob. mass of the rectangle  $R_1 = R^d(a_1^*, a_1, a_2^*, b_2^*, \dots, a_d^*, b_d^*)$  exactly  $\frac{\epsilon}{2d}$ . Similarly, let  $a_2, a_3, \dots, a_d^*$  be numbers such that prob. masses of  $R_2 = R^d(a_1^*, b_1^*, a_2^*, a_2, \dots, a_d^*, b_d^*)$ ,  $\dots$ ,  $R_d = R^d(a_1^*, b_1^*, \dots, a_d^*, a_d)$  are exactly  $\frac{\epsilon}{2d}$ . And let  $b_1, b_2, \dots, b_d$  be such numbers that prob. masses of  $R_{d+1} = R^d(b_1, b_1^*, a_2^*, b_2^*, \dots, a_d^*, b_d^*)$ ,  $\dots$ ,  $R_{2d} = R^d(a_1^*, b_1^*, \dots, a_d^*, b_d)$  are all exactly  $\frac{\epsilon}{2d}$ . Let  $R(S)$  be the rectangle generated by  $A$ .

Similarly to  $\mathbb{R}^2$  case, we can show that  $R(S) \subseteq R^*$ . Since probab. masses of each of  $R_i$ ,  $i \in [2d]$  is exactly  $\frac{\epsilon}{2d}$ , probability mass of the rectangle  $R^d(a_1, b_1, a_2, b_2, \dots, a_d, b_d)$  is at least  $1 - \epsilon$ . Since  $R(S) \subseteq R^d(a_1, b_1, a_2, b_2, \dots, a_d, b_d)$

If  $S$  contains positive examples in all of the  $R_i$ , then  $R^d(a_1, b_1, \dots, a_d, b_d)$  will be fully

contained within  $R(S)$  and, therefore,  $R(S)$  will have the probability mass of at least  $1 - \epsilon$ .

Hence, hypothesis returned by will have an error of at most  $\epsilon$ .

Now, let  $m$  be the size of the training set. Then, for each point in the set, probability that it is not contained within  $R_i$  is  $1 - \frac{\epsilon}{2d}$  for each  $i \in [2d]$ . Hence, for each  $i \in [2d]$ , the probab. that  $S$  doesn't contain an ~~exam~~ example in  $R_i$  will be  $(1 - \frac{\epsilon}{2d})^m$ . Then, probab. that  $S$  doesn't contain positive example in at least one of  $R_i$ ,  $i \in [2d]$ , will be equal to  $2d (1 - \frac{\epsilon}{2d})^m$ , which is smaller or equal to  $2d e^{(-\frac{\epsilon}{2d})m}$ .

Hence, the probab. that the hypothesis returned by  $A$  has error of at most  $\epsilon$  is larger or equal to  $1 - 2d e^{(-\frac{\epsilon}{2d})m}$ . Let's denote this probability  $1 - \sigma$ .

Then,  $\sigma \leq 4e^{-\frac{\epsilon}{2d}m}$  and, therefore,  $m \geq \frac{2d \log(\frac{2d}{\sigma})}{\epsilon}$

Hence, if  $A$  receives a training set of the size  $m \geq \frac{2d \log(2d/\sigma)}{\epsilon}$ , then with probability of at least  $1 - \sigma$ , it returns a hypothesis with error of at most  $\epsilon$ .
